In addition to structural abnormalities of the diaphragm, congenital diaphragmatic hernia (CDH) presents with severe hypoplasia of lung tissue involving both the pulmonary vasculature and the airways. These developmental defects often yield a severe phenotype of pulmonary hypertension (PH) and lung function impairment. Despite adequate surgical repair of the diaphragm, neonatal mortality of CDH remains high, due to ineffectiveness of inhaled nitric oxide (NO) and absence of alternative therapy for PH in the newborn.

Russo *et al*<sup>1</sup> demonstrate that maternally administered sildenafil reaches therapeutic levels in the rabbit fetus, without toxicity for mother or the fetus. CDH fetuses treated with sildenafil demonstrated increased pulmonary vascular branching compared with placebo-treated fetuses. The improved vascularisation was paralleled by reduced pulmonary artery pressure and by morphological changes in the lung parenchyma and functional improvement. In line with previous rodent studies, Russo *et al*<sup>1</sup> found that the decreased lung weight due to CDH is not rescued in sildenafil-treated fetuses with CDH, suggesting that the sildenafil-induced improvement of vascular and alveolar development contributes to the lung maturation more than the volume growth. These well-performed studies obtained in an animal model that closely resembles both the pharmacokinetics of human pregnancy and alveolar development in humans provide a next step towards a clinically useful therapy for CDH and its postnatal consequences.

In addition to providing relevant steps towards clinical development of sildenafil as a potential therapy for CDH, Russo *et al* give valuable insights into the mechanisms of lung development. Stressing the key role of cyclic guanosine monophosphate (cGMP)/NO signalling in CDH pathophysiology, the study provides additional support for the idea that appropriate vascularisation critically determines final structure and function of the lung.<sup>2</sup> The first mechanism suggested here is the involvement of vascular endothelial growth factor (VEGF), as the sildenafil-induced improvement in vascularisation and alveolar maturation was paralleled by an increase in VEGF expression in parenchymal cells. VEGF is of paramount importance in lung development,<sup>3 4</sup> as it contributes to pulmonary angiogenesis and vessel growth, with subsequent alveolar maturation and adequate matching of ventilation and perfusion.<sup>3</sup> During normal lung development, VEGF is secreted by lung mesenchymal and alveolar epithelial cells, creating an parenchymal VEGF gradient<sup>5</sup> that coordinates bronchovascular growth (figure 1). The decreased VEGF expression in the lung parenchyma, as

described by Russo *et al*, is a consistent finding in CDH, both in humans<sup>6</sup> and in animal models.<sup>7</sup> Reduced VEGF directly impairs lung development, as a number of studies have shown that decreased VEGF expression *per se* (eg, by heterozygous knockout of the hypoxia-inducible factor (HIF)-2 $\alpha$  or by pharmacological VEGF-receptor inhibitors like SU-5416) is sufficient to induce the phenotype of hypovascularisation, alveolar immaturity and PH.<sup>8 9</sup> This is further supported by observations in bronchopulmonary dysplasia, a lung developmental disorder that shares many features with CDH, including impaired VEGF expression, decreased vascular branching and impaired alveolar maturation.<sup>10 11</sup> In bronchopulmonary dysplasia, VEGF gene therapy reversed the phenotype of decreased vascular branching and alveolar maturation<sup>12</sup> and could be mimicked by sildenafil treatment.<sup>11</sup>

As sildenafil was primarily developed to mimic the action of NO, a second mechanism involved here may be the NO/cGMP signalling. Although not directly addressed in this paper, earlier rodent studies demonstrated that CDH pups have increased phosphodiesterase type 5 (PDE5) activity, paralleled by reduced cGMP and endothelial NO synthase (eNOS) concentrations.<sup>7</sup> Like VEGF, lung vascular development is dependent on intact NO/cGMP signalling. Cigarette smoke studies have shown the critical dependence of endothelial cells on eNOS phosphorylation and NO secretion for endothelial tube formation and vasculogenesis, which could be rescued by NO donors.<sup>13</sup> In line with these *in vitro* data, animal studies demonstrated that cigarette smoke-induced impairment of NO signalling results in PH and loss of alveoli.<sup>14</sup> Of interest here, cigarette smoke-exposed mice and guinea pigs show pulmonary vascular remodelling before alveolar loss occurs, thereby stressing the dependence of mature lung parenchyma on vascularisation. This suggests that vascular changes may even underlie overt airway diseases in adults like emphysema/COPD,<sup>15</sup> thus supporting recent insights that emphysema is "...characterized by a failure in cell and molecular maintenance programs necessary for proper lung development".<sup>16</sup> Thus, VEGF-dependent and NO/cGMP-dependent vascular growth and maintenance are key determinants of lung function.

An important issue that remains to be addressed is why CDH leads to decreased VEGF. Although data from bronchopulmonary hypoplasia models point toward dysregulation of HIF-1 $\alpha$  and HIF-2 $\alpha$  signalling,<sup>17</sup> no mechanistic studies have been performed to answer this question in CDH. Future studies focusing on this question may yield valuable insights in gene regulation programmes in

**Figure 1** Illustration showing vascular endothelial growth factor (VEGF)-driven angiogenesis in normal lung development and congenital diaphragmatic hernia (CDH). (A) VEGF is secreted by lung parenchyma and the tip of growing airways in which VEGF production may be regulated by cyclic guanosine monophosphate (cGMP)-mediated hypoxia-inducible factor (HIF) activation. VEGF-driven angiogenesis matches perfusion to ventilation, thus creating a mature alveolocapillary unit. (B) In CDH, increased phosphodiesterase type 5 (PDE5) activity suppresses VEGF expression, which can be treated with sildenafil.

pulmonary development. A second question is whether and how VEGF and NO/cGMP signalling are linked. The observation that expression levels of VEGF and eNOS/cGMP are both decreased in CDH and are both enhanced by sildenafil<sup>7</sup> suggests that VEGF and eNOS/cGMP share a common pathway. In the classical pathway, VEGF stimulates eNOS, which leads to NO release which may in turn stimulate cGMP. This pathway, however, does not explain why sildenafil enhances VEGF expression, as VEGF acts upstream of cGMP in this pathway. Alternatively, VEGF expression may be increased downstream of NO release, as reported before.<sup>18</sup> The last possibility is that VEGF is under direct control of PDE5/cGMP and exerts its effects via eNOS/NO signalling (figure 1). This signalling pathway has been described by Park *et al*<sup>11</sup> who demonstrated that sildenafil inhibits PDE5, which in turn leads to cGMP-activated HIF signalling. A third and final issue that requires further study is the effect of sildenafil on healthy pups. Russo *et al* demonstrate that in normal fetuses antenatal sildenafil administration decreases vascular branching. This may reflect a fine-tuned balance in cGMP activity. Although cGMP is required for cell survival and angiogenesis, sustained exposure of high cGMP levels also leads to cell death and apoptosis in lung endothelial cells,<sup>19</sup> thus suggesting a defined window of cGMP activity in which it promotes pulmonary angiogenesis, whereas vascular growth is inhibited when cGMP is outside this window.

What are the next steps for further development of this treatment toward clinical application? Fetal and maternal toxicity are well studied by Russo *et al*, but postnatal toxicity and effects on long-term development remain inconclusive. Although rodent studies demonstrated that transplacental sildenafil administration does not affect rodent brain development and function,<sup>7</sup> future studies are required to evaluate the effect of transplacental sildenafil on postnatal parameters of safety and efficacy.

In conclusion, these studies point towards VEGF/NO-dependent vascular branching as a crucial step in the late development and maturation of the alveolocapillary unit. In adult animals, VEGF/NO signalling is necessary for maintenance of lung tissue architecture and regeneration. Sildenafil enhances

expression of both VEGF and eNOS/cGMP and may thus be a strong stimulus for pulmonary angiogenesis and vasculogenesis. The dependence on VEGF for development and maintenance links developmental disorders to adult disease and may extend the results of the current study well beyond CDH alone.
